Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

The invention relates to valves for pressurised dispensing containers and more particularly to valves for dispensing metered doses from a pressurised dispensing container.

Known metering valves for pressurised dispensing containers usually have a metering chamber within the valve, the metering chamber having seals at its upper and lower end and being filled with a fresh dose of product to be dispensed immediately after the previous dose has been dispensed. A valve stem slides through the seals and is movable between an inoperative position where the metering chamber is filled with product to be dispensed and an operative position in which the metered dose of product is dispensed through the valve stem. The valve stem is spring urged into its inoperative position. In the past, the metering chamber has usually been defined by a component within a housing of the valve and the usual practice has been to locate the spring inside the metering chamber. This has tended to detract from the provision of accurately metered doses from the valve and there has generally been no provision for allowing different predetermined sizes of metering chamber within the valve.

It is also known from BG-1 280 229 (Green) to define the volume of the metering chamber by means of an insert received within a cavity of the housing and for one of the seals to be trapped between the insert and a shoulder formed by the housing. The insert has a predetermined interior capacity so that the metered dose can be varied by replacing the insert by a new insert having a different capacity.

The invention provides a valve for dispensing metered doses from a pressurised dispensing container and comprising a valve housing, means within the housing defining a metering chamber, first and second valve seals closing off opposed ends of the metering chamber and a valve stem in sliding engagement with apertures in the seals and extending therethrough, the valve stem including an outlet orifice and an inlet orifice which communicates with the metering chamber when the valve stem is in an operative position, the valve stem being spring urged into an inoperative position by a spring located within the valve housing outside the metering chamber and characterised by having a sub-assembly located in the housing comprising inner and outer nested components, one of the valve seals being trapped between the nested components and the volume of the metering chamber being defined by means of the inner component.

Preferably, portions of said nested components between which said valve seal is trapped include cut-away portions adjacent the aperture through which the valve stem extends, said cut-away portions being arranged to facilitate flexing the valve seal, to allow ingress of pressurised medium past the valve seal to the valve housing.

The cutaway portions may comprise castellations, a different number of castellations being

formed in said inner and outer nested components. In one embodiment, there are six castellations on the inner components and four on the outer component.

Preferably there is a spring retaining cup fitting over the inner end of the valve stem within the housing the spring being located between a portion of said cup and an end wall of the valve housing.

In a preferred embodiment, all the components of the valve except said first and second seals are of metal. This is particularly important in certain applications where the valve is intended to dispense pharmaceutical products which might be affected by deterioration of plastics components within the valve.

Preferably the valve further comprises a valve cup for attaching the valve to a container. The particular type of valve cup will be determined by the container to which the valve is to be attached.

The invention also provides a pressurised pre-dispensing container including a valve as described above.

A preferred embodiment of the invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a section through a metering valve according to the invention with its valve stem in a first, inoperative, position;

Figure 2 is a view similar to Figure 1 but with the valve stem partially depressed to a second position;

Figure 3 is a view similar to Figures 1 and 2 but with the valve stem fully depressed to an operative position;

Figure 4 is a plan view of a component of the metering chamber of the valve of Figure 1, and,

Figure 5 is a plan view of another component of the metering chamber of the valve of Figure 1.

Referring first to Figure 1, a metering valve 10 for an aerosol container comprises the following main components:

A valve housing 11, a valve stem 12, a valve cup 13, first and second seals 14, 15 and a metering chamber 16.

The valve housing 11 is of generally cylindrical configuration, closed at one end 18 and having an enlarged diameter portion 19 at its other, open, end which provides a seat for the metering chamber 16. Between the ends 18 and 19 of the valve housing 11, the housing comprises first and second cylindrical portions 20, 21 of differing diameter, these sections being joined by a frusto-conical portion 22. Orifices 23 formed in the cylindrical portion 21 adjacent the end portion 19 provide communication between the interior of the valve housing 11 and an aerosol container 17 to which the valve is attached, in use. The open end 19 of the valve housing fits within a central cylindrical portion 25 of the valve cup 13 and is retained in position by an annular indentation 26 in the valve cup.

As can be seen in the drawings, the valve cup 13 comprises a second cylindrical portion 28 of considerably greater diameter than the portion 25,

the two cylindrical portions being joined by a radially extending portion 29 of generally S shaped cross-section. The exact shape of the portions 28, 29 of the valve cup will depend on the container to which the valve is to be attached. The configuration shown in the drawings is typical for attachment to an ordinary aerosol container but different configurations may be provided if the valve is to be attached to a bottle or a roll neck container. The valve cup 13 is attached to the aerosol container or bottle in known conventional manner, a gasket 27 being provided to form a seal between the valve cup 13 and the container.

The metering chamber 16 is located within the valve housing 11 and co-axial therewith. The metering chamber 16 is formed from two components, inner and outer chamber components 30, 31 respectively. The outer chamber component 31 is a cylindrical member having an inturned portion 33 at one end and an outwardly turned annular flange 34 at the other end. The inner chamber portion 30 has an inwardly turned end 36 adjacent to end 33 of chamber portion 31 and, at its other end, an outwardly and upwardly turned portion 38. The portion 38 of chamber component 30 provides a seating for the first seal 14 which is clamped between the annular shoulder defined by the portion 38 and the upper end 39 of the valve cup. The chamber component 31 fits around the chamber component 30 as shown in Figures 1 to 3 and is retained in assembled, nested, relation therewith by its portion 34 being clamped between the underside of portion 38 of chamber component 30 and the annular shoulder defined by portion 19 of the valve cup 11. The second seal 15 of the valve is located between portions 33 and 36 of chamber components 31 and 30 respectively.

As can be seen more clearly in Figures 4 and 5, portions 33 and 36 of chamber components 31, 30 are provided with castellations. In the particular embodiment shown, portion 33 has four castellations 41 while portion 36 has six castellations 42. Although the number of castellations provided in portion 33, 36 is not critical, the numbers of castellations in the two portions should differ. The castellations are provided for a purpose to be described below.

It will be appreciated that the size of the metering chamber is defined by chamber component 30. The size of the chamber may therefore be varied by altering the shape of component 30. Consequential alteration of the shape of component 31 will then also be required so that the components 30, 31 still fit together in nested relation. It will be appreciated that altering the size and shape of the sub-assembly of components 30, 31 need not affect the other components in the valve or the assembly of the valve. In order to provide metering chambers of different size, the central portion of chamber component 30 may include a reduced diameter portion or its length may be altered while the end portions 36, 38 of chamber component 30 remain unaltered. At extremes of size, the necessary alteration of chamber compo-

nent 30 may require consequential minor alterations to other parts of the valve. For example, with very short components 30 the valve stem may require modification and for very large metering chambers, the valve body 11 may be of a larger diameter.

As can be seen in Figures 1 to 3, the assembled metering chamber components and seal 15 have a central aperture 44 provided therein and aligned apertures 45, 46 are provided in the first seal 14 and the upper end 39 of the valve cup 13.

The valve stem 12 is a sliding fit in these apertures. The valve stem 12 is a hollow generally cylindrical tube having an outlet orifice 48 at its upper end and an inlet aperture 49 formed in its side wall at the position shown in the drawings. The valve stem includes an enlarged diameter portion 50 which, in the position shown in Figure 1, seats on the first seal 14 and thereby defines the upper most position of the valve stem. The lower end of the valve stem is closed and includes an inverted wall portion 52 which extends from the lower end of the valve stem for approximately one third of its length to a position above the seal 15 when the valve is in its inoperative position shown in Figure 1. The inverted wall portion 52 defines a channel extending axially along the valve stem. The length of this channel may vary as the length of chamber component 30 is varied.

A cup shaped member 55 fits around the lower end of the valve stem 12 and includes an outwardly turned portion 56 defining an annular shoulder which provides a seating for one end of a spring 60. The spring 60 urges the valve stem into its inoperative position as shown in Figure 1 and the other end of the spring 60 seats on the lower end wall of the valve housing 11.

With the exception of the first and second seals 14, 15 which are of a known rubber compound, and the gasket 27 which is also usually rubber, all the components of the valve 10 are formed from metal. In one example, the valve cup 13, and spring retaining cup 55 are of aluminium while the remaining components of the valve are of stainless steel. The provision of a metering valve which does not include any plastics components has advantages in applications where deterioration of the plastics components within the valve might result from the material being dispensed from the aerosol container to which the valve is attached. This is particularly important in some pharmaceutical applications.

The operation of the valve 10 is as follows. The valve is designed for use in an inverted position. In the description of the components of the valve above, references have been made to upper and lower ends of components and this describes the valve in the position shown in Figures 1 to 3 which is its normal upright position when it is attached to a can or bottle and that can or bottle is standing upright. This is the usual rest position. However, the valve is inverted in use, that is rotated through 180° from the position shown in Figures 1 to 3.

Referring now to Figure 1 which shows the

valve in its inoperative position and imagining the valve to be inverted, it will be appreciated that the contents of the container to which the valve is attached, that is the product to be dispensed, will flow through apertures 23 to fill the valve cup 11. From the valve cup 11, the product will also flow via passage 52 into the metering chamber 16 and thereby fill the metering chamber. In the position shown in Figure 1, the product will not be released from the metering chamber because the first valve seal 14 is in sealing contact around the valve stem 12, and abutting the enlarged diameter portion 50.

When it is desired to dispense a metered dose of product through the valve 10, the valve stem 12 is depressed (that is moved downwardly with respect to the position shown in Figure 1) until the valve stem reaches the position shown in Figure 2 relative to the other components of the valve. In the position shown in Figure 2, the valve stem has reached a position where the passage 52 is no longer providing a flow path between the interior of the metering chamber 16 and the interior of the valve cup 11. As shown in Figure 2, the passage 52 is now below the second valve seal 15 which is now in sealing contact with the valve stem thereby isolating the metering chamber from the valve cup 11. However, in the position shown in Figure 2, the metered dose of product which is now contained in the metering chamber 16 has not yet started to be dispensed because the inlet aperture 49 to the valve stem 12 is still above the first valve seal 14 which is still in sealing contact around the valve stem. In the position shown in Figure 2 therefore, a metered dose of product is contained in the metering chamber which is now isolated.

Upon further depression of the valve stem, the stem moves to the position shown in Figure 3 relative to the other components of the valve. In this position, the valve stem is still in sealing contact with the lower valve seal 15 so that no product may enter the metering chamber 16. However, the inlet aperture 49 has now passed through the upper valve seal 14 so that the metering chamber is in communication with the interior of the valve stem and thence with the outlet aperture 48 from the valve stem. The metered dose of product contained in the metering chamber thereby passes out through the valve stem to be dispensed.

When the valve stem is released, the spring 60 returns the valve stem from the position shown in Figure 3 to the position shown in Figure 2 where the inlet aperture 49 is again closed off and thence to the position shown in Figure 1 where the metering chamber 16 is again in communication with the interior of the valve housing 11 and is thereby refilled with the product to be dispensed.

The operation of the valve as described above is the normal sequence of operation when the valve is attached to an aerosol container which is filled with product to be dispensed, the product being under pressure. It is usual for the valve to be attached to a container which is empty, the con-

tainer then being filled with the product and pressure medium. The valve 10 is designed to facilitate such a filling operation. It is usual for such a filling operation to be conducted by placing a filling head over the valve. The filling head depresses the valve stem and forces product and pressure medium through and around the valve stem and thence into the metering chamber. The castellations 41, 42 formed in the components 30, 31 of the metering chamber are so arranged that, during this filling operation, they allow the second valve seal 15 to deflect thereby allowing product and pressure medium to pass through the seal 15 and thence through the valve housing 11 and into the container to which the valve is attached. It will be appreciated that the differing number of castellations in the two chamber components 30, 31 ensures that the castellations will never all be axially aligned so that an adequate seating for the second valve seal 15 is provided while still allowing adequate deflection of the valve seal during the filling operation.

The invention is not limited to the embodiment described above and various modifications may be made. For example, although the valve described is intended for use in an inverted position, a similar valve may be provided for upright operation. In this case, the apertures 23 will not be provided in the valve cup 11 which instead will have an inlet aperture at its lower end and a dip tube connected to that inlet aperture will extend to a position adjacent the bottom of the container to which the valve is attached.

Furthermore as described above, the size of the metering chamber may be predetermined by substituting for the chamber components 30, 31 alternative appropriately shaped components.

Still further, the castellations formed on the chamber components 30, 31 may be replaced by cut-outs of different shape around the periphery of the central aperture of those components.

Claims

1. A valve for dispensing metered doses from a pressurised dispensing container and comprising a valve housing (11), means (30, 31) within the housing defining a metering chamber (16), first and second valve seals (14, 15) closing off opposed ends of the metering chamber and a valve stem (12) in sliding engagement with apertures in the seals and extending therethrough, the valve stem including an outlet orifice (48) and an inlet orifice (49) which communicates with the metering chamber when the valve stem is in an operative position, the valve stem being spring urged into an inoperative position by a spring (60) located within the valve housing outside the metering chamber and characterised by having a sub-assembly located in the housing comprising inner and outer nested components (30, 31), one of the valve seals (15) being trapped between the nested components and the volume of the metering chamber being defined by means of the inner component.

2. A valve as claimed in claim 1 characterised in

that portions of said nested components (30, 31) between which said valve seal (15) is trapped include cut-away portions (41, 42) adjacent the aperture (44) through which the valve stem (12) extends, said cut-away portions being arranged to facilitate flexing the valve seal, to allow ingress of pressurised medium past the valve seal to the valve housing (11).

3. A valve as claimed in claim 2 characterized in that the cut-away portions (41, 42) comprise castellations, a different number of castellations being formed in said inner and outer nested components (30, 31).

4. A valve as claimed in claim 3 characterized in that there are six castellations (42) on the inner component (30) and four (41) on the outer component (31).

5. A valve as claimed in any one of the preceding claims characterized in that a spring retaining cup (55) fits over the inner end of the valve stem (12) within the valve housing (11), the spring being located between a portion (56) of said cup and an end wall (18) of the valve housing.

6. A valve as claimed in any one of the preceding claims characterized in that all the components of the valve except said first and second seals (14, 15) are of metal.

7. A valve as claimed in any one of the preceding claims characterized in that it further comprises a valve cup (13) for attaching the valve to a container.

8. A valve as claimed in claim 7 characterized in that said inner and outer nested components (30, 31) locate in a seat (19) formed in the valve housing (11) and the valve housing is attached to the valve cup (13) thereby to retain the valve components in assembled relation.

9. A valve as claimed in claim 8 characterized in that the other valve seal (14) is located between a seat (38) formed in said inner nested component (30) and a wall portion (39) of the valve cup (13).

10. A pressurised dispensing container characterized by including a valve as claimed in any one of the preceding claims.

Patentansprüche

1. Ventil zur Abgabe von zugemessenen Mengen aus einem unter Druck stehenden Abgabebehälter, welches ein Ventilgehäuse (11), eine Einrichtung (30, 31) in dem Gehäuse, welche eine Zumesskammer (16) bildet, erste und zweite Ventildichtungen (14, 15), die die gegenüberliegenden Enden der Zumesskammer absperren, und einen Ventilschaft (12) aufweist, der in Gleiteingriff mit Öffnungen in den Dichtungen ist und durch diese geht, wobei der Ventilschaft eine Auslassöffnung (48) und eine Einlassöffnung (49) enthält, die mit der Zumesskammer in Verbindung steht, wenn der Ventilschaft in seiner Arbeitsstellung ist, und wobei der Ventilschaft in eine Ausserbetriebsstellung mittels einer Feder (60) federbelastet ist, die in dem Ventilgehäuse ausserhalb der Zumesskammern angeordnet ist, dadurch gekennzeichnet, dass eine Unterbaugruppe in dem

Gehäuse vorgesehen ist, die innere und äussere, ineinandergeschachtelte Bauteile (30, 31) aufweist, wobei eine der Ventildichtungen (15) zwischen den ineinandergeschachtelten angeordneten Bauteilen eingeschlossen ist, und das Volumen der Zumesskammern durch das innere Bauteil bestimmt wird.

2. Ventil nach Anspruch 1, dadurch gekennzeichnet, dass die Teile der ineinandergeschachtelt angeordneten Bauteile (30, 31), zwischen denen die Ventildichtung (15) eingeschlossen ist, ausgenommene Abschnitte (41, 42) in der Nähe der Öffnung (44) umfassen, durch die der Ventilschaft (12) geht, wobei die ausgenommenen Abschnitte derart beschaffen sind, dass das Biegen der Ventildichtung unterstützt wird, um ein Eintreten des unter Druck stehenden Mediums an der Ventildichtung vorbei zu dem Ventilgehäuse (11) zu gestatten.

3. Ventil nach Anspruch 2, dadurch gekennzeichnet, dass die ausgenommenen Abschnitte (41, 42) kronenförmig ausgebildete Teile umfassen, wobei eine unterschiedliche Anzahl von kronenförmig ausgenommenen Teilen in den inneren und äusseren, ineinandergeschachtelt angeordneten Bauteilen (30, 31) vorgesehen ist.

4. Ventil nach Anspruch 3, dadurch gekennzeichnet, dass sechs kronenförmige Ausnehmungen (42) auf dem inneren Bauteil (30) und vier (41) auf dem äusseren Bauteil (31) vorgesehen sind.

5. Ventil nach einem der vorangehenden Ansprüche, dadurch gekennzeichnet, dass eine Federhalteschale (55) passend über dem inneren Ende des Ventilschaftes (12) in dem Ventilgehäuse (11) angeordnet ist, und dass die Feder zwischen einem Abschnitt (56) der Schale und einer Stirnwand (18) des Ventilgehäuses vorgesehen ist.

6. Ventil nach einem der vorangehenden Ansprüche, dadurch gekennzeichnet, dass alle Bauteile des Ventils abgesehen von den ersten und zweiten Dichtungen (14, 15) aus Metall hergestellt sind.

7. Ventil nach einem der vorangehenden Ansprüche, dadurch gekennzeichnet, dass es ferner eine Ventiltasse (13) zum Anbringen des Ventils an einem Behälter aufweist.

8. Ventil nach Anspruch 7, dadurch gekennzeichnet, dass die inneren und äusseren ineinandergeschachtelt angeordneten Bauteile (30, 31) in einem Sitz (19) liegen, der in dem Ventilgehäuse (11) ausgebildet ist, und dass das Ventilgehäuse an der Ventiltasse (13) hierdurch angebracht ist, um die Ventilbauteile im zusammengebauten Zustand festzulegen.

9. Ventil nach Anspruch 8, dadurch gekennzeichnet, dass die andere Ventildichtung (14) zwischen einem Sitz (38), der in dem inneren, ineinandergeschachtelt angeordneten Bauteil (30) ausgebildet ist, und einem Wandabschnitt (39) der Ventiltasse (13) vorgesehen ist.

10. Unter Druck gesetzter Abgabebehälter, dadurch gekennzeichnet, dass er ein Ventil gemäss einem der vorangehenden Ansprüche enthält.

Revendications

1. Valve destinée à distribuer des doses mesurées à partir d'un récipient distributeur pressurisé et comprenant un boîtier de valve (11), des moyens (30, 31) définissant à l'intérieur du boîtier une chambre de dosage (16), un premier et un second joints d'étanchéité de valve (14, 15) étanchant des extrémités opposées de la chambre de dosage et une tige de valve (12) engagée à coulissement dans des ouvertures des joints d'étanchéité et les traversant, la tige de valve présentant un orifice de sortie (48) et un orifice d'entrée (49) qui communique avec la chambre de dosage quand la tige de valve est en position active, la tige de valve étant sollicitée élastiquement vers une position inactive par un ressort (60) placé dans le corps de valve à l'extérieur de la chambre de dosage et caractérisée en ce qu'elle comporte un sous-ensemble placé dans le boîtier comprenant des composants emboîtés intérieur et extérieur (30, 31), l'un des joints d'étanchéité de valve (15) étant emprisonné entre les éléments emboîtés et le volume de la chambre de dosage étant défini au moyen du composant intérieur.

2. Valve selon la revendication 1 caractérisée en ce que les parties desdits composants emboîtés (30, 31) entre lesquelles ledit joint d'étanchéité de valve (15) est emprisonné présentent des échancrures (41, 42) voisines de l'ouverture (44) que traverse la tige de valve (12), lesdites échancrures étant disposées en sorte de faciliter les flexions du joint d'étanchéité de valve, pour permettre l'entrée du milieu pressurisé à travers le joint d'étanchéité de valve dans le boîtier de valve (11).

3. Valve selon la revendication 2 caractérisée en ce que les échancrures (41, 42) sont constituées par des crêneaux, des crêneaux en nombre diffé-

rents étant ménagés dans lesdits composés emboîtés intérieur et extérieur (30, 31).

4. Valve selon la revendication 3 caractérisée en ce qu'il y a six crêneaux (42) sur le composant intérieur (30) et quatre crêneaux (41) sur le composant extérieur (31).

5. Valve selon l'une quelconque des revendications précédentes caractérisée en ce qu'une coupelle de retenue de ressort (55) s'emboîte sur l'extrémité intérieure de la tige de valve (12) à l'intérieur du boîtier de valve (11), le ressort étant placé entre une partie (56) de ladite coupelle et une paroi d'extrémité (18) du corps de valve.

6. Valve selon l'une quelconque des revendications précédentes caractérisée en ce que tous les composants de la valve sauf lesdits premier et second joints d'étanchéité (14, 15) sont en métal.

7. Valve selon l'une quelconque des revendications précédentes caractérisée en ce qu'elle comprend encore une coupelle de valve (13) pour la fixation de la valve à un récipient.

8. Valve selon la revendication 7 caractérisée en ce que lesdits composants emboîtés intérieur et extérieur (30, 31) se logent dans un siège (19) ménagé dans le boîtier de valve (11) et le boîtier de valve est fixé à la coupelle de valve (13) pour maintenir par là les composants de la valve en relation d'assemblage.

9. Valve selon la revendication 8 caractérisée en ce que l'autre joint d'étanchéité de vanne (14) est placé entre un siège (38) ménagé dans ledit composant emboîté intérieur (30) et une partie de paroi (39) de la coupelle de valve (13).

10. Récipient distributeur pressurisé caractérisé en ce qu'il comporte une valve selon l'une quelconque des revendications précédentes.
